

## A. Find Minimum Operations

1 second, 256 megabytes

You are given two integers  $n$  and  $k$ .

In one operation, you can subtract any power of  $k$  from  $n$ . Formally, in one operation, you can replace  $n$  by  $(n - k^x)$  for any non-negative integer  $x$ .

Find the minimum number of operations required to make  $n$  equal to 0.

**Input**

Each test contains multiple test cases. The first line contains the number of test cases  $t$  ( $1 \leq t \leq 10^4$ ). The description of the test cases follows.

The only line of each test case contains two integers  $n$  and  $k$  ( $1 \leq n, k \leq 10^9$ ).

**Output**

For each test case, output the minimum number of operations on a new line.

input
6 5 2 3 5 16 4 100 3 6492 10 10 1
output
2 3 1 4 21 10

In the first test case,  $n = 5$  and  $k = 2$ . We can perform the following sequence of operations:

1. Subtract  $2^0 = 1$  from 5. The current value of  $n$  becomes  $5 - 1 = 4$ .
2. Subtract  $2^2 = 4$  from 4. The current value of  $n$  becomes  $4 - 4 = 0$ .

It can be shown that there is no way to make  $n$  equal to 0 in less than 2 operations. Thus, 2 is the answer.

In the second test case,  $n = 3$  and  $k = 5$ . We can perform the following sequence of operations:

1. Subtract  $5^0 = 1$  from 3. The current value of  $n$  becomes  $3 - 1 = 2$ .
2. Subtract  $5^0 = 1$  from 2. The current value of  $n$  becomes  $2 - 1 = 1$ .
3. Subtract  $5^0 = 1$  from 1. The current value of  $n$  becomes  $1 - 1 = 0$ .

It can be shown that there is no way to make  $n$  equal to 0 in less than 3 operations. Thus, 3 is the answer.

Find the smallest suitable  $n$  such that after performing the operations there will be exactly  $k$  bulbs on. We can show that an answer always exists.

† An integer  $x$  is divisible by  $y$  if there exists an integer  $z$  such that  $x = y \cdot z$ .

**Input**

Each test contains multiple test cases. The first line contains the number of test cases  $t$  ( $1 \leq t \leq 10^4$ ). The description of the test cases follows.

The only line of each test case contains a single integer  $k$  ( $1 \leq k \leq 10^{18}$ ).

**Output**

For each test case, output  $n$  — the minimum number of bulbs.

input
3 1 3 8
output
2 5 11

In the first test case, the minimum number of bulbs is 2. Let's denote the state of all bulbs with an array, where 1 corresponds to a turned on bulb, and 0 corresponds to a turned off bulb. Initially, the array is  $[1, 1]$ .

- After performing the operation with  $i = 1$ , the array becomes  $[0, 0]$ .
- After performing the operation with  $i = 2$ , the array becomes  $[0, 1]$ .

In the end, there are  $k = 1$  bulbs on. We can also show that the answer cannot be less than 2.

In the second test case, the minimum number of bulbs is 5. Initially, the array is  $[1, 1, 1, 1, 1]$ .

- After performing the operation with  $i = 1$ , the array becomes  $[0, 0, 0, 0, 0]$ .
- After performing the operation with  $i = 2$ , the array becomes  $[0, 1, 0, 1, 0]$ .
- After performing the operation with  $i = 3$ , the array becomes  $[0, 1, 1, 1, 0]$ .
- After performing the operation with  $i = 4$ , the array becomes  $[0, 1, 1, 0, 0]$ .
- After performing the operation with  $i = 5$ , the array becomes  $[0, 1, 1, 0, 1]$ .

In the end, there are  $k = 3$  bulbs on. We can also show that the answer cannot be smaller than 5.

The problem statement has recently been changed. [View the changes.](#)

## B. Brightness Begins

1 second, 256 megabytes

Imagine you have  $n$  light bulbs numbered  $1, 2, \dots, n$ . Initially, all bulbs are on. To flip the state of a bulb means to turn it off if it used to be on, and to turn it on otherwise.

Next, you do the following:

- for each  $i = 1, 2, \dots, n$ , flip the state of all bulbs  $j$  such that  $j$  is divisible by  $i^{\dagger}$ .

After performing all operations, there will be several bulbs that are still on. Your goal is to make this number exactly  $k$ .

## C. Bitwise Balancing

2 seconds, 256 megabytes

You are given three non-negative integers  $b$ ,  $c$ , and  $d$ .

Please find a non-negative integer  $a \in [0, 2^{61}]$  such that  $(a | b) - (a \& c) = d$ , where  $|$  and  $\&$  denote the bitwise OR operation and the bitwise AND operation, respectively.

If such an  $a$  exists, print its value. If there is no solution, print a single integer  $-1$ . If there are multiple solutions, print any of them.

**Input**

Each test contains multiple test cases. The first line contains the number of test cases  $t$  ( $1 \leq t \leq 10^5$ ). The description of the test cases follows.

The only line of each test case contains three positive integers  $b$ ,  $c$ , and  $d$  ( $0 \leq b, c, d \leq 10^{18}$ ).

Output

For each test case, output the value of  $a$ , or  $-1$  if there is no solution. Please note that  $a$  must be non-negative and cannot exceed  $2^{61}$ .

input
3 2 2 2 4 2 6 10 2 14
output
0 -1 12

In the first test case,  $(0 \mid 2) - (0 \& 2) = 2 - 0 = 2$ . So,  $a = 0$  is a correct answer.

In the second test case, no value of  $a$  satisfies the equation.

In the third test case,  $(12 \mid 10) - (12 \& 2) = 14 - 0 = 14$ . So,  $a = 12$  is a correct answer.

D. Connect the Dots

2 seconds, 512 megabytes

One fine evening, Alice sat down to play the classic game "Connect the Dots", but with a twist.

To play the game, Alice draws a straight line and marks  $n$  points on it, indexed from 1 to  $n$ . Initially, there are no arcs between the points, so they are all disjoint. After that, Alice performs  $m$  operations of the following type:

- She picks three integers  $a_i, d_i$  ( $1 \leq d_i \leq 10$ ), and  $k_i$ .
- She selects points  $a_i, a_i + d_i, a_i + 2d_i, a_i + 3d_i, \dots, a_i + k_i \cdot d_i$  and connects each pair of these points with arcs.

After performing all  $m$  operations, she wants to know the number of connected components<sup>†</sup> these points form. Please help her find this number.

<sup>†</sup> Two points are said to be in one connected component if there is a path between them via several (possibly zero) arcs and other points.

Input

Each test contains multiple test cases. The first line contains the number of test cases  $t$  ( $1 \leq t \leq 10^5$ ). The description of the test cases follows.

The first line of each test case contains two integers  $n$  and  $m$  ( $1 \leq n \leq 2 \cdot 10^5, 1 \leq m \leq 2 \cdot 10^5$ ).

The  $i$ -th of the following  $m$  lines contains three integers  $a_i, d_i$ , and  $k_i$  ( $1 \leq a_i \leq a_i + k_i \cdot d_i \leq n, 1 \leq d_i \leq 10, 0 \leq k_i \leq n$ ).

It is guaranteed that both the sum of  $n$  and the sum of  $m$  over all test cases do not exceed  $2 \cdot 10^5$ .

Output

For each test case, output the number of connected components.

input
3 10 2 1 2 4 2 2 4 100 1 19 2 4 100 3 1 2 5 7 2 6 17 2 31
output
2 96 61

In the first test case, there are  $n = 10$  points. The first operation joins the points 1, 3, 5, 7, and 9. The second operation joins the points 2, 4, 6, 8, and 10. There are thus two connected components:  $\{1, 3, 5, 7, 9\}$  and  $\{2, 4, 6, 8, 10\}$ .

In the second test case, there are  $n = 100$  points. The only operation joins the points 19, 21, 23, 25, and 27. Now all of them form a single connected component of size 5. The other 95 points form single-point connected components. Thus, the answer is  $1 + 95 = 96$ .

In the third test case, there are  $n = 100$  points. After the operations, all odd points from 1 to 79 will be in one connected component of size 40. The other 60 points form single-point connected components. Thus, the answer is  $1 + 60 = 61$ .

E. Expected Power

4 seconds, 256 megabytes

You are given an array of  $n$  integers  $a_1, a_2, \dots, a_n$ . You are also given an array  $p_1, p_2, \dots, p_n$ .

Let  $S$  denote the random **multiset** (i. e., it may contain equal elements) constructed as follows:

- Initially,  $S$  is empty.
- For each  $i$  from 1 to  $n$ , insert  $a_i$  into  $S$  with probability  $\frac{p_i}{10^4}$ . Note that each element is inserted independently.

Denote  $f(S)$  as the **bitwise XOR** of all elements of  $S$ . Please calculate the expected value of  $(f(S))^2$ . Output the answer modulo  $10^9 + 7$ .

Formally, let  $M = 10^9 + 7$ . It can be shown that the answer can be expressed as an irreducible fraction  $\frac{p}{q}$ , where  $p$  and  $q$  are integers and  $q \not\equiv 0 \pmod{M}$ . Output the integer equal to  $p \cdot q^{-1} \pmod{M}$ . In other words, output such an integer  $x$  that  $0 \leq x < M$  and  $x \cdot q \equiv p \pmod{M}$ .

Input

Each test contains multiple test cases. The first line contains the number of test cases  $t$  ( $1 \leq t \leq 10^4$ ). The description of the test cases follows.

The first line of each test case contains a single integer  $n$  ( $1 \leq n \leq 2 \cdot 10^5$ ).

The second line of each test case contains  $n$  integers  $a_1, a_2, \dots, a_n$  ( $1 \leq a_i \leq 1023$ ).

The third line of each test case contains  $n$  integers  $p_1, p_2, \dots, p_n$  ( $1 \leq p_i \leq 10^4$ ).

It is guaranteed that the sum of  $n$  over all test cases does not exceed  $2 \cdot 10^5$ .

Output

For each test case, output the expected value of  $(f(S))^2$ , modulo  $10^9 + 7$ .

input
4 2 1 2 5000 5000 2 1 1 1000 2000 6 343 624 675 451 902 820 6536 5326 7648 2165 9430 5428 1 1 10000
output
500000007 820000006 280120536 1

In the first test case,  $a = [1, 2]$  and each element is inserted into  $S$  with probability  $\frac{1}{2}$ , since  $p_1 = p_2 = 5000$  and  $\frac{p_i}{10^4} = \frac{1}{2}$ . Thus, there are 4 outcomes for  $S$ , each happening with the same probability of  $\frac{1}{4}$ :

- $S = \varnothing$ . In this case,  $f(S) = 0, (f(S))^2 = 0$ .
- $S = \{1\}$ . In this case,  $f(S) = 1, (f(S))^2 = 1$ .
- $S = \{2\}$ . In this case,  $f(S) = 2, (f(S))^2 = 4$ .
- $S = \{1, 2\}$ . In this case,  $f(S) = 1 \oplus 2 = 3, (f(S))^2 = 9$ .

Hence, the answer is  $0 \cdot \frac{1}{4} + 1 \cdot \frac{1}{4} + 4 \cdot \frac{1}{4} + 9 \cdot \frac{1}{4} = \frac{14}{4} = \frac{7}{2} \equiv 500\,000\,007 \pmod{10^9 + 7}$ .

In the second test case,  $a = [1, 1]$ ,  $a_1$  is inserted into  $S$  with probability 0.1, while  $a_2$  is inserted into  $S$  with probability 0.2. There are 3 outcomes for  $S$ :

- $S = \varnothing$ . In this case,  $f(S) = 0, (f(S))^2 = 0$ . This happens with probability  $(1 - 0.1) \cdot (1 - 0.2) = 0.72$ .
- $S = \{1\}$ . In this case,  $f(S) = 1, (f(S))^2 = 1$ . This happens with probability  $(1 - 0.1) \cdot 0.2 + 0.1 \cdot (1 - 0.2) = 0.26$ .
- $S = \{1, 1\}$ . In this case,  $f(S) = 0, (f(S))^2 = 0$ . This happens with probability  $0.1 \cdot 0.2 = 0.02$ .

Hence, the answer is  $0 \cdot 0.72 + 1 \cdot 0.26 + 0 \cdot 0.02 = 0.26 = \frac{26}{100} \equiv 820\,000\,006 \pmod{10^9 + 7}$ .

## F. Count Leaves

4 seconds, 256 megabytes

Let  $n$  and  $d$  be positive integers. We build the *divisor tree*  $T_{n,d}$  as follows:

- The root of the tree is a node marked with number  $n$ . This is the 0-th layer of the tree.
- For each  $i$  from 0 to  $d - 1$ , for each vertex of the  $i$ -th layer, do the following. If the current vertex is marked with  $x$ , create its children and mark them with all possible distinct divisors<sup>†</sup> of  $x$ . These children will be in the  $(i + 1)$ -st layer.
- The vertices on the  $d$ -th layer are the leaves of the tree.

For example,  $T_{6,2}$  (the divisor tree for  $n = 6$  and  $d = 2$ ) looks like this:

Define  $f(n, d)$  as the number of leaves in  $T_{n,d}$ .

Given integers  $n, k$ , and  $d$ , please compute  $\sum_{i=1}^n f(i^k, d)$ , modulo  $10^9 + 7$ .

<sup>†</sup> In this problem, we say that an integer  $y$  is a divisor of  $x$  if  $y \geq 1$  and there exists an integer  $z$  such that  $x = y \cdot z$ .

### Input

Each test contains multiple test cases. The first line contains the number of test cases  $t$  ( $1 \leq t \leq 10^4$ ). The description of the test cases follows.

The only line of each test case contains three integers  $n, k$ , and  $d$  ( $1 \leq n \leq 10^9, 1 \leq k, d \leq 10^5$ ).

It is guaranteed that the sum of  $n$  over all test cases does not exceed  $10^9$ .

### Output

For each test case, output  $\sum_{i=1}^n f(i^k, d)$ , modulo  $10^9 + 7$ .

input
3 6 1 1 1 3 3 10 1 2
output
14 1 53

In the first test case,  $n = 6, k = 1$ , and  $d = 1$ . Thus, we need to find the total number of leaves in the divisor trees  $T_{1,1}, T_{2,1}, T_{3,1}, T_{4,1}, T_{5,1}, T_{6,1}$ .

- $T_{1,1}$  has only one leaf, which is marked with 1.
  - $T_{2,1}$  has two leaves, marked with 1 and 2.
  - $T_{3,1}$  has two leaves, marked with 1 and 3.
  - $T_{4,1}$  has three leaves, marked with 1, 2, and 4.
  - $T_{5,1}$  has two leaves, marked with 1 and 5.
  - $T_{6,1}$  has four leaves, marked with 1, 2, 3, and 6.
- The total number of leaves is  $1 + 2 + 2 + 3 + 2 + 4 = 14$ .

In the second test case,  $n = 1, k = 3, d = 3$ . Thus, we need to find the number of leaves in  $T_{1,3}$ , because  $1^3 = 1$ . This tree has only one leaf, so the answer is 1.
